
PyMVG Documentation

Release 1.0

Andrew Straw

August 02, 2015

1	Ecosystem	3
2	Development	5
2.1	PyMVG file format	5
2.2	Plotting utilities	6
2.3	Camera Model	6
2.4	API Reference	7
3	Indices and tables	9

PyMVG is a Python implementation of various computational camera geometry operations.

Features:

- triangulate 2D features from multiple calibrated cameras into a single 3D point (using algorithm from [the classic textbook by Hartley & Zisserman](#)). [\[example\]](#)
- load/save camera calibrations from ROS (which uses OpenCV)
- load/save camera system calibrations from [MultiCamSelfCal](#)
- complete implementation of OpenCV camera model in pure Python in a [single file](#) for easy understanding
- complete implementation of DLT camera calibration procedure
- completely vectorized code for rapid operation on many points using [numpy](#)
- completely written in [Python](#)
- plotting utilities [\[example 1\]](#) [\[example 2\]](#)

It contains a complete re-implementation of the OpenCV camera model and can thus use calibrations made by or for OpenCV. PyMVG is entirely written in Python, and thus – depending on your preferences – it may be significantly easier to understand than the equivalent OpenCV implementation. PyMVG makes extensive use of [numpy](#), and thus when called on large batches of points, is no slower than native code.

Ecosystem

PyMVG is designed to interoperate with [OpenCV](#), [ROS](#), and [MultiCamSelfCal](#). Unit tests ensure exact compatibility with the relevant parts of these packages.

See also [opengl-hz](#).

Development

All development is done on our [github repository](#).

2.1 PyMVG file format

The PyMVG file format specifies a camera system completely. The file is valid JSON. Here is an example that specifies a system of 3 cameras:

```
{ "__pymvg_file_version__": "1.0",
  "camera_system": [
    { "name": "cam1",
      "width": 640,
      "height": 480,
      "P": [[ 320.0, 0, 319.99999999999994, 0 ],
            [ 0, 320.00000000000006, 240.0, 0 ],
            [ 0, 0, 1.0, 0 ]],
      "K": [[ 320.0, 0, 319.99999999999994 ],
            [ 0, 320.00000000000006, 240.0 ],
            [ 0, 0, 1.0 ]],
      "D": [ 0.2, 0.3, 0.1, 0.1, 0.1 ],
      "R": [[ 1.0, 0, 0 ],
            [ 0, 1.0, 0 ],
            [ 0, 0, 1.0 ]],
      "Q": [[ -1.0000000000000004, 0, 0 ],
            [ 0, 1.0, 0 ],
            [ 0, 0, -1.0000000000000004 ]],
      "translation": [ 0, 0, 0.9000000000000005 ]
    },
    { "name": "cam2",
      "width": 640,
      "height": 480,
      "P": [[ 320.0, 0, 319.99999999999994, 0 ],
            [ 0, 320.00000000000006, 240.0, 0 ],
            [ 0, 0, 1.0, 0 ]],
      "K": [[ 320.0, 0, 319.99999999999994 ],
            [ 0, 320.00000000000006, 240.0 ],
            [ 0, 0, 1.0 ]],
      "D": [ 0, 0, 0, 0, 0 ],
      "R": [[ 1.0, 0, 0 ],
            [ 0, 1.0, 0 ],
            [ 0, 0, 1.0 ]],
      "Q": [[ 0, 0, 0.9999999999999999 ],
```

```
[ 0.847998304005088, 0.5299989400031799, 0 ],

"translation": [ 0, 0, 0.9433981132056602 ]
},
{"name": "cam3",
"width": 640,
"height": 480,
"P": [[ 320.0, 0, 319.99999999999994, 0 ],
[ 0, 320.00000000000006, 240.0, 0 ],
[ 0, 0, 1.0, 0 ]],
"K": [[ 320.0, 0, 319.99999999999994 ],
[ 0, 320.00000000000006, 240.0 ],
[ 0, 0, 1.0 ]],
"D": [ 0, 0, 0, 0, 0 ],
"R": [[ 1.0, 0, 0 ],
[ 0, 1.0, 0 ],
[ 0, 0, 1.0 ]],
"Q": [[ 0, 0, 1.0000000000000002 ],
[ -0.7071067811865475, 0.7071067811865477, 0 ],
[ -0.7071067811865478, -0.7071067811865475, 0 ]],
"translation": [ 0, 0, 0.7071067811865475 ]
}
]
```

2.2 Plotting utilities

Given the above example, we can plot the camera system.

```
from pymvg import CameraModel, MultiCameraSystem
from pymvg.plot_utils import plot_system

import os

import matplotlib.pyplot as plt
from mpl_toolkits.mplot3d import Axes3D

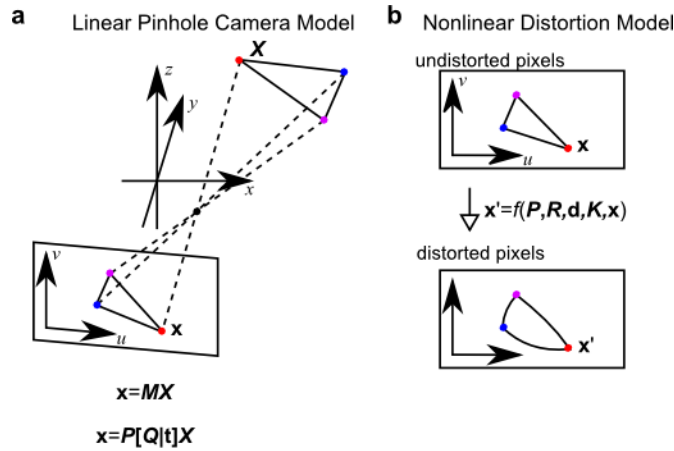

fname = os.path.join('.', 'pymvg_camsystem_example.json')
system = MultiCameraSystem.from_pymvg_file( fname )

fig = plt.figure()
ax = fig.add_subplot(1,1,1, projection='3d')
plot_system( ax, system )
ax.set_xlabel('x'); ax.set_ylabel('y'); ax.set_zlabel('z')
ax.set_xlim(-0.8,0.8); ax.set_ylim(-0.8,0.8); ax.set_zlim(-0.8,0.8)
plt.show()
```

2.3 Camera Model

2.3.1 single camera model

The core of PyMVG is a camera model that is compatible with the calibration outputs of [OpenCV](#) and [MultiCamSelf-Cal](#).

In the above image, you can see that this camera model consists of a linear pinhole projection model followed by a nonlinear distortion model. The pinhole model is specified completely by the 3×4 matrix M (or, equivalently, the 3×3 intrinsic matrix P , the 3×3 ortho-normal rotation matrix Q , and the translation vector t). The nonlinear distortion model is specified completely by elements of the intrinsic matrix of the pinhole model and several distortion terms.

2.3.2 camera system (multiple cameras)

PyMVG represents a camera system with the `MultiCameraSystem` class. You create an instance with a list of individual camera instances. The class provides additional methods for triangulation of 3D points and so on.

2.4 API Reference

class `pymvg.camera_model.CameraModel` (*name, width, height, _rquat, _camcenter, P, K, distortion, rect*)

an implementation of the Camera Model used by ROS and OpenCV

Transformations: We can think about the overall projection to 2D in two steps. Step 1 takes 3D world coordinates and, with a simple matrix multiplication and perspective division, projects them to undistorted 2D coordinates. Step 2 takes these undistorted 2D coordinates and distorts them so they are ‘distorted’ and match up with a real camera with radial distortion, for example.

3D world \rightarrow (step1) \rightarrow undistorted 2D \rightarrow (step2) \rightarrow distorted 2D

Step 1 is accomplished by making the world coordinates a homogeneous vector of length 4, multiplying by a 3×4 matrix M (built from P , R and t) to get values $[r, s, t]$ in which the undistorted 2D coordinates are $[r/t, s/t]$. (The implementation is vectorized so that in fact many points at once can be transformed.)

Step 2 is somewhat complicated in that it allows a separate focal length and camera center to be used for distortion. Undistorted 2D coordinates are transformed first to uncorrected normalized image coordinates using parameters from P , then corrected using a rectification matrix. These corrected normalized image coordinates are then used in conjunction with the distortion model to create distorted normalized pixels which are finally transformed to distorted image pixels by K .

Coordinate system: the camera is looking at $+Z$, with $+X$ rightward and $+Y$ down. For more information, see http://www.ros.org/wiki/image_pipeline/CameraInfo

As noted on the link above, this differs from the coordinate system of Harley and Zisserman, which has Z forward, Y up, and X to the left (looking towards $+Z$).’

camcenter_like (*nparr*)

create numpy array of camcenters like another array

get_aligned_camera (*scale, rotation, translation*)
return a copy of this camera with new extrinsic coordinates

get_flipped_camera ()
return a copy of this camera looking in the opposite direction

The returned camera has the same 3D->2D projection. (The 2D->3D projection results in a vector in the opposite direction.)

get_mirror_camera (*axis='lr', hold_center=False*)
return a copy of this camera whose x coordinate is (image_width-x)

get_view_camera (*eye, lookat, up=None*)
return a copy of this camera with new extrinsic coordinates

is_distorted_and_skewed (*max_skew_ratio=1000000000000000.0*)
True if pixels are skewed and distorted

is_opencv_compatible ()
True iff there is no skew

classmethod load_camera_from_M (*pmat, width=None, height=None, name='cam', distortion_coefficients=None, _depth=0, eps=1e-15*)
create CameraModel instance from a camera matrix M

classmethod load_camera_from_opened_bagfile (*bag, extrinsics_required=True*)
factory function for class CameraModel

bag - an opened rosbag.Bag instance extrinsics_required - are extrinsic parameters required

project_3d_to_camera_frame (*pts3d*)
take 3D coordinates in world frame and convert to camera frame

project_camera_frame_to_3d (*pts3d*)
take 3D coordinates in camera frame and convert to world frame

save_to_bagfile (*fname, roslib*)
save CameraModel to ROS bag file

fname - filename or file descriptor to save to roslib - the roslib module

class pymvg.multi_camera_system.**MultiCameraSystem** (*cameras*)

find3d (*pts, undistort=True*)
Find 3D coordinate using all data given

Implements a linear triangulation method to find a 3D point. For example, see Hartley & Zisserman section 12.2 (p.312).

By default, this function will undistort 2D points before finding a 3D point.

classmethod from_mcsc (*dirname*)
create MultiCameraSystem from output directory of MultiCamSelfCal

get_aligned_copy (*other*)
return copy of self that is scaled, translated, and rotated to best match other

Indices and tables
